---

Šotnár K & Obuch J 2009: Feeding ecology of a nesting population of the Common Buzzard (*Buteo buteo*) in the Upper Nitra region, Central Slovakia. Slovak Rapt J 3: 13–20.

**Abstract:** During routine checks of the nests of the Common Buzzard in the Upper Nitra region (Central Slovakia) we collected food remains and recorded all prey given to the nestlings. We present results from the period 2006–2008. 606 food items were determined, comprising mainly mammals (67%). Birds were also frequent (17%), less so amphibians and reptiles (7%) and invertebrates (10%). During the rodent population peak in 2007, Buzzard pairs nesting in the valley preyed mainly on *Microtus arvalis*, whereas pairs living at the rim of the valley fed on *Myodes glareolus* and *Talpa europaea*, and higher in the Vtáčnik Mts birds fed on *Apodemus flavicollis*. After a massive decline in the rodent population in the following year 2008, the survival rate of the nestlings was very low and the proportion of invertebrates in their diet increased. Birds that were most frequently preyed upon included juvenile *Turdus philomelos* and *Garrulus glandarius*, prey identified from amphibian was mainly *Bufo bufo*, and from reptile prey was largely *Anguis fragilis*.

**Abstrakt:** Pri kontrolách hniezd myšiaka hôrneho v oblasti horného Ponitria (stredné Slovensko) sme zbierali zvyšky jeho potravy a zaznamenávali korisť, prinesenú mláďatám. Prezentujeme výsledky z rokov 2006–2008. Determinovali sme 606 kusov potravy, v ktorej dominujú cicavce (67 %). Početné sú aj vtáky (17 %), obojživelníky a plazy (7 %) a bezstavovce (10 %). Pri vysokej populačnej hladine hlodavcov v roku 2007 bol u párov, hniezdiacich v kotline, dominantnou korisťou druh *Microtus arvalis*, na okraji kotliny druhy *Myodes glareolus* a *Talpa europaea* a u párov, hniezdiacich vyššie v pohorí Vtáčnik druh *Apodemus flavicollis*. Po silnom poklese populačnej hladiny hlodavcov v nasledujúcom roku 2008 bola nízka úspešnosť hniezdenia myšiakov a v ich potrave stúpol podiel bezstavovcov. Z vtákov boli najčastejšie lovené mláďatá druhov *Turdus philomelos* a *Garrulus glandarius*, z obojživelníkov *Bufo bufo* a z plazov *Anguis fragilis*.

**Key words:** *Buteo buteo*, diet, Upper Nitra region, Central Slovakia

**Acknowledgments:** We owe our gratitude to Martin Dúbrava and Branislav Beniska who physically examined the Buzzard nests, collected pellets and food remains of the Common Buzzard in the Upper Nitra region.

#### Introduction

In contrast to owls, bones are digested to a greater degree in the pellets of birds of prey. Therefore the investigation of their diet requires employing several different methods. During the nesting period, examination of pellets, determination of bone and feather remains in the nest can be used, as well as recording prey items presented to the nestlings. Prey remains in the nests of the *Buteo buteo* were evaluated by Šotnár (2003, 2007). In South Moravia this method was used for examining the food of the *B. buteo* by Voříšek et al. (1997) and Horák & Matušík (2000), a smaller sample from the Czech Republic and

Moravia was examined by Toufar (1958). In Germany, the same method was used to examine the food of *B. buteo* by Wuttky (1963) and Mebs (1964).

In the past when birds of prey were hunted legally and shot individuals were concentrated in taxidermist workshops, the stomach content of the birds could be examined. Sládek (1961, 1966) used this method in cooperation with the taxidermist workshop in Žiar nad Hronom. In the same manner, Sabadoš & Sládek (1968) studied the diet of the birds of prey shot in the pheasant reserve during an exceptionally harsh winter. Ševčík (1980) examined the food of the Buzzards shot in the pheasant reserves in the

Czech Republic. Extensive material collected by Rörig from Germany was studied by Uttendörfer (1939).

Comprehensive data from Central Europe is summarized in the papers of Glutz et al. (1989) and Cramp & Simmons (1980). Our aim was to evaluate and compare the diet of the Common Buzzard population in three nesting seasons and three elevation zones of the Upper Nitra region.

### Material and Methods

In 2006–2008 we collected pellets and recorded food remains in the nests of the Common Buzzard in the Upper Nitra region. Nests were examined in May–July. Our work builds upon the study by Šotnár & Topercer (2009). Collected material was classified into two categories:

**Provisions** – visual examination of food items. Determination of whole individuals, food remains, feather and fur directly in the nest.

**Pellets** – analysis of pellets and bone remains. All samples were processed in 5% NaOH solution to dissolve the feather and hair material. Bone fragments were used for the determination of vertebrate prey and elytrae and jaws were used to determine invertebrates. Mammals were determined according to cranial fragments, moles were also identified using humerus, Microtids using the lower molar teeth  $M_1$ . Birds were determined according to 5 types of bone fragments: beaks, *humerus*, *metatarsus* and *tarsometatarsus*. Reptiles were determined according to jaws, skeletons and skin or scale remains. Food samples collected in 2007 and 2008 were classified into 3 zones:

**A.** Nesting pairs from the valley, coline zone 300–500 m a. s. l. (agrocenoses, field forests, riparian vegetation, 42 samples);

**B.** Nesting pairs from the piedmont area of Vtáčnik Mts, submontane zone 500–700 m a. s. l. (forest edge up to 1 km deep into the forest, 36 samples);

**C.** Nesting pairs from the mountain range Vtáčnik Mts., montane zone 700–1100 m a. s. l. (deep in the forests, approximately 2–5 km from the rim of the valley, 15 samples).

To evaluate the results in the Table 1–4 the method of marked differences from the mean (MDFM; Obuch 2001) was used. In the tables samples are sorted according to their similarity. Species in the upper part of the table are sorted that those with marked positive deviations are arranged in blocks bordered by solid lines. Species with less marked deviations are sorted under the dashed line according to descending frequency. Those with frequency less than 5 are shown in Table 1. The lower part of the table shows sums for individual vertebrate and invertebrate classes. The diversity index  $H'$  is calculated according to the formula of Shannon & Weaver (1949).

### Results

In 2006–2008 we studied food remains in the nests of *B. buteo* and determined 606 prey items. The most dominant part of the diet comprised mammals (Mammalia, 67%), less frequent were birds (Aves, 17%), amphibians and

reptiles (Amphibia and Reptilia, 7%; Fig. 1–7). Invertebrates (Evertabrata, 10%) are numerous, but comprise an insignificant part of the total biomass.

The most dominant prey species *Microtus arvalis* (26.6%) was less frequent in 2008, *Talpa europaea* (18.7%) is equally frequent in samples from 2006, 2007 and 2008, *Apodemus flavicollis* (5.9%) is more frequent in 2007. The lack of rodents in 2008 is partially compensated by increased proportion of invertebrates, including mainly insects of the orders Coleoptera and Hymenoptera (Table 1). The most frequent mammals include *Myodes glareolus* (8.6%) and *Sorex araneus* (2.2%). From birds *B. buteo* fed most frequently on juveniles of *Turdus philomelos* (2.8%) and *Garrulus glandarius* (2.6%). *Bufo bufo* (1.8%) was among the most frequent amphibian prey and *Anguis fragilis* (1.3%) was the most frequent reptile.

a – pellets / vývržky; b – nest supply / zásoba na hniezde

The pellets revealed three times more prey items than food provisions in the nests. Therefore the comparison of species composition using the MDFM method (Table 2) showed marked differences only in the less frequent material collected in the nests. The pellets comprised mainly mammals (77.7%), including *M. arvalis*, *M. glareolus* and *A. flavicollis*. Coleopterans were the most frequent invertebrate prey. Nest provisions included mainly birds (Aves, 60.4%), namely *G. glandarius*, *T. philomelos*, *Sturnus vulgaris* and *Coccothraustes coccothraustes*.

The evaluation of *B. buteo* diet composition in relation to habitat was strongly influenced by the gradation of rodents in 2007 and the subsequent decline combined with unfavourable weather conditions in 2008. Great abundance of food in 2007 was reflected in the higher nesting success. Therefore in 2007 we collected a three times larger sample of food than in 2008. In 2007 the most frequent prey item of *B. buteo* in the valley included *M. arvalis* (51.4%), in the piedmont of Vtáčnik, *M. glareolus* and *T. europaea* were more frequent in the montane zone, *A. flavicollis* was dominant. In 2008, Aves and Evertabrata were more frequent in the valley and *T. europaea* and Evertabrata in the piedmont area. The montane zone yielded only a small sample of 22 food items. Notable prey items included *Aegolius funereus*, *Strix aluco* and *Locustella fluviatilis*.

## Discussion

Our data on the food composition of *B. buteo* from the Upper Nitra valley, which were collected through the analysis of pellets and food provisions in the nests, corresponds with the results of other authors using similar methods in South Bohemia and Germany. Since the works of Voříšek et al. (1997) and Horák & Matušík (2000) only include prey determined to higher taxonomic levels, we decided to make comparison in Table 4 only with our own data from the determination of pellets at Pálava. All four studies on the diet of *B. buteo*, used in the comparison, show a lower proportion of the dominant species *M. arvalis* and higher proportion of the subdominant *T. europaea*. Birds can be seen in higher proportion, especially *G. glandarius* and *T. philomelos* species. In contrast to other studies, our results show higher proportion of *S. araneus*, *A. flavicollis*, *C. coccothraustes* and *Elaphe longissima*. In our results we also included findings of dead *B. buteo* nestlings, killed mainly as a result of cainism during the shortage of food in 2008. Studies using similar methods found other species more abundant such as *Apodemus sylvaticus*, *Arvicola terrestris*, *Lacerta agilis*, *A. fragilis* (Mebs 1964) *Lepus europaeus*, *Alauda arvensis* (Mebs 1964, Wuttky 1963), *Cricetus cricetus*,

*Emberiza citrinella*, *Columba livia domestica* (Wuttky 1963) and Coleoptera (Voříšek et al. 1997; Table 4).

The papers focusing on the examination of stomach contents more frequently studied winter samples, dominated mainly by *M. arvalis*. Stomach contents of Common Buzzards shot in the pheasant reserves more often included *Phasianus colchicus* and *Gallus gallus domestica* species (Ševčík 1980). Invertebrates are usually better preserved in stomach samples than vertebrates, therefore Coleoptera, Orthoptera (Sládek 1961), as well as Lepidopteran larvae (caterpillars) were often found in the stomach contents (Ševčík 1980, Uttendörfer 1939).

According to our study from the Upper Nitra, small game (hare, pheasant, grey partridge) comprises less than 1% of the Common Buzzard's diet. Several authors (Sládek 1966, Horák & Matušík 2000) suggested that small game were not originally preyed upon by *B. buteo* and that it only fed on their carcasses.

**Apom** – *Aquila pomarina* (Dravecký et al. 2008, central Slovakia / stredné Slovensko), **Bbut** – *Buteo buteo* (own data / vlastné údaje), **Agen** – *Accipiter gentilis* (Šotnár 2000)

A study of the diet of two similar sized birds of prey; *Accipiter gentilis* (Šotnár 2000) and *Aquila pomarina* (Dravecký et al. 2008) carried out in Upper Nitra region were studied in the Upper Nitra region: compare their diets (Tab. 5). In *A. pomarina* greater proportion of the diet comprises *M. arvalis* and several other non-sylvatic vole species: *M. agrestis* and *A. terrestris*. The most frequently

hunted frog species include *R. temporaria*, whereas *B. buteo* hunts *B. bufo* more frequently. *A. gentilis* is markedly specialized to hunting birds (92% of the diet), few mammals killed include mainly *Sciurus vulgaris*. Block comparison of species comprising the majority of the diet shown in Tab. 5 reveals that the food niches of these 3 larger bird of prey species have a minimal overlap.
